

“On the Effect of the Spectrum on the Haloid Salts of Silver.”

By Captain W. DE W. ABNEY, C.B., R.E., D.C.L., F.R.S.,  
and G. S. EDWARDS, C.E. Received November 26,—Read  
December 12, 1889.

In 1881 one of us gave, in the ‘Proceedings of the Royal Society,’ a paper with the same title as the above. Since then, however, he has been able to work out a more exact means of measuring the effect of the spectrum on these salts of silver, and it is our desire now to lay the improved results before the Society.

In January, 1887, one of us read a paper before the Photographic Society of Great Britain, “On the mode of measuring Densities of Photographic Deposits, with some remarks on Sensitometers,” and in it alluded to the possibility of measuring the relative sensitiveness of a photographic plate to the different parts of the spectrum. The plan there indicated, with some instrumental improvements, has been employed in the present instance.

The method employed consists in throwing an image of the photographed spectrum on a white screen and measuring the density of the photograph at different points. As the spectrum of sun light abounds in dark Fraunhofer lines, it was evident that the sun would be a very inconvenient source of light by which to form the spectrum. It was also inconvenient on account of the variation in intensity at different times of the year and day in its different parts. After trials of various sources of light we came to the conclusion that the most practical source to employ was the light from gas, burnt in an Argand burner. A somewhat whiter light would have been better, perhaps, since the ultra-violet rays would have been stronger; but it appeared that, taking all things into consideration, the convenience of gas light more than counter-balanced its disadvantages. We may mention that the crater of the positive pole of the electric light was used in some instances; but, as certain minima of action on some of the salts of silver experimented with lay at parts of the spectrum where bright carbon bands were to be found, the main researches were carried out by the aid of gas light.

The apparatus employed for photographing the spectrum was that employed in the previous research already alluded to. The two prisms employed were of medium dense white flint, each having an angle of  $62^{\circ}$ . The collimating lens was of the same material, and the photographic lens was a rapid rectilinear doublet by Dalmeyer, of 16-inch focal length. In some cases one of the lenses of the doublet was dismantled, and the other used as a single lens, giving a focal length of about 30 inches. An image of the gas flame was thrown

on the slit of the collimator, producing a bright image when the slit had a width of  $\frac{1}{200}$  of an inch. The bottom half of the slit was closed by a shutter when the gas spectrum was photographed. To know the locality of the part of the gas spectrum impressed, a second spectrum of the electric arc was photographed below the gas spectrum, lithium and sodium being volatilised, to give a sufficient number of fiducial lines. The plate was then withdrawn from the slide and placed in an apparatus by which a series of small square portions of the plate lying parallel and below the last-named spectrum could be exposed at will.

The exposures of this series of squares varied between  $3\frac{1}{4}$  seconds and 5 minutes, generally being  $3\frac{1}{4}$ ,  $7\frac{1}{2}$ , 15, 30, 60, 90, 120, 180, 240, and 300 seconds. The exposure was made to the light from an Argand paraffin lamp placed at 6 feet from the plate. When the height of the flame was kept constant, no practical difference in illumination was found, and no variation was found during a series of exposures if the lamp were allowed to attain a constant temperature by burning ten minutes. The plate thus impressed with the various images was developed in the ordinary manner with the proper developer.

If a gelatine plate were used, ferrous oxalate was usually employed; whilst acidified sulphate of iron was employed if a collodion wet plate were being experimented with. It has not been thought worth while to record all the measurements of the various plates, but a selection has been made of the most important results. It may be remarked that only 5 per cent. addition of bromo-iodide of silver to a bromide of silver emulsion sufficed to shift the place of maximum sensitiveness of the plate from the blue towards the green, as shown in the diagram. After development the plates were fixed as usual and dried, and were then ready for measuring. The following diagram shows the apparatus employed for the measurement, the description of which is taken from a previous paper by one of us.

A is the source of light—gas, paraffin, or other lamp; B is a lens of about 9 inches focus, used as a condenser; C is a double frame for carrying the negative, N, which has an upward and side motion, so that any part of the negative may be brought in front of the condenser; D is a lens on a stand, used to focus the negative on the screen E, which is black except one small square, as shown, where the image of the part to be measured is thrown; F is one of a series of diaphragms used with D for the purpose of sharpening the image and reducing its brightness when required; H is the rod used to cast the shadow on the white patch; G is a flat mirror reflecting a beam also on E; K is the rotating apparatus placed in the path of the light reflected from G, to diminish it at pleasure; M is the small electro-motor which drives K. The rod H is so placed that the shadows

cast by the beam from G, and coming through the negative, just touch, and the two are equalised in brightness by means of opening more or less the rotating sectors K.

The negative to be measured was marked with a scale of  $\frac{1}{24}$  inches, and, in cases of sudden change of density, to less. It was then placed in the measuring apparatus and measurements commenced. When the square patches were measured, a thickish rod was employed, but for the photographed spectrum a knitting needle,  $\frac{1}{8}$  of an inch thick, was substituted. The opacities of the different parts of the film were calculated from where the negative showed "no deposit," and the opening of the sectors when the direct and reflected light balanced was taken as the standard. The required opening of the sectors showed but little variation for any of the photographs.

The scale of density corresponding to different times of exposure was plotted from the readings of squares, and the readings of the different parts of the photographed spectra were applied to the curve so derived, and the density corresponding to the times of exposure tabulated. From the photographed spectrum of the arc the positions of the different measured densities were known and the curve with the reference Fraunhofer lines plotted in the usual manner. From these curves the curves for the normal or wave-length spectrum were calculated, and it is these curves which are shown in the accompanying figures.

Reverting to the paper to which we have referred ('Roy. Soc. Proc.,' No. 217, 1881), it will be seen that the figures therein shown differ from those here given. This is caused by the fact that the former curves were only eye estimations of density, whilst the latter are the comparative sensitiveness derived from measured densities.

That the former are not in great error will be seen by comparing the place of maximum density of the former with the place of maximum sensitiveness of the latter.

It may be well to remark here on one point to which objection might be taken in the results. It has been assumed in making the scale that length of exposure is equivalent to the intensity of the light. This is not a hasty assumption, but has been carefully tested. When the exposure is but the minute fraction of a second, then the substitution of length of exposure for intensity does not apparently hold good; but, when the exposures are such as are given to the scale, the substitution is perfectly legitimate.

In the following tables the curves of the simple haloid salts of silver are given, as well as mixtures of two or more, and also double salts. Where double salts of silver are shown they were prepared by mixing the alkaline salts in proper equivalent proportions, and then emulsifying in gelatine or collodion by adding the requisite amount of silver nitrate to them. Where simple mixtures are shown, emulsions containing the proper equivalent amount of the silver salts were prepared and subsequently mixed. It has been deemed desirable to give the values for the haloid salts when stained with certain dyes, such as are usually employed in rendering photographic plates what is termed isochromatic. Attention is called to the fact that a mixture of solutions of two dyes does not render the salts of the same sensitiveness to different parts of the spectrum as do the two dyes if applied separately, washing taking place between the application of each. For erythrosin Mallman's well known formula was used to obtain the coloured solution. The erythrosin was obtained from Germany, and showed only traces of fluorescence. The cyanin was obtained from Messrs. Hopkin and Williams, and appears to be made after Greville Williams' formula. When cyanin was employed, 5 grains was dissolved in 1 oz. of alcohol, and water added to make up to 2 ozs. This solution was poured over the plate, which was then allowed to dry. The plate was then washed with equal parts of spirit and water, and finally with water, and then exposed to the spectrum. Similar results were obtained whether the film was dry or moist.

[In all the tables except VII, VIII, IX, X, XV, and XVI, the following are the points on the scale numbers of the principal Fraunhofer lines: H, 13·8; G, 10·9; Li, 9; F, 7·6; E, 6·0; D, 4·3; Li, 2·8.

In Tables VIII and IX the following are to be substituted: H, 14·0; G, 11·0; Li, 9·0; F, 7·7; E, 6·2; D, 4·6; Li, 3·1.

In Tables VII, X, XV, and XVI the following are to be substituted: H, 6·7; G, 9; Li, 10·7; F, 12·1; E, 13; D, 14·3; Li, 15·7.

FIG. 1.

AgBr.

FIG. 2.

AgCl.

FIG. 3.

$\text{Ag}_2\text{BrI}$ .

FIG. 4.

Chloro-bromide.

FIG. 5.

FIG. 6.

FIG. 7.

$\frac{3}{4}\text{AgCl}$  }  
 $\frac{1}{4}\text{AgI}$  }

FIG. 8.

$\frac{3}{4}\text{AgCl}$  }  
 $\frac{1}{4}\text{AgBr}$  }

FIG. 9.

FIG. 10.

FIG. 11.

AgCl stained with erythrosin.

FIG. 12.

$\left. \begin{matrix} \frac{3}{4} \text{AgBr} \\ \frac{1}{4} \text{AgI} \end{matrix} \right\}$  Stained with erythrosin and cyanin.

FIG. 13.

Edwards' isochromatic.

FIG. 14.

Edwards' isochromatic treated with cyanin.

FIG. 1.

FIG. 2.

FIG. 3.

$\text{Ag}_2\text{BrI}$ .

FIG. 4.

Chloro-bromide.

FIG. 5.

I is  $\left. \begin{array}{l} \frac{3}{4}\text{AgBr} \\ \frac{1}{4}\text{AgI} \end{array} \right\}$

II is  $\left. \begin{array}{l} \frac{3}{4}\text{AgBr} \\ \frac{1}{4}\text{AgI} \end{array} \right\}$  Dyed with erythrosin.

FIG. 6.

I is  $\left. \begin{array}{l} \frac{1}{2} \text{AgBr} \\ \frac{1}{2} \text{AgI} \end{array} \right\}$

II is  $\left. \begin{array}{l} \frac{1}{2} \text{AgBr} \\ \frac{1}{2} \text{AgI} \end{array} \right\}$  Stained with erythrosin.

FIG. 7.

FIG. 8.

FIG. 9.

FIG. 10.

AgBr stained with erythrosin.

FIG. 11.

AgCl stained with erythrosin.

FIG. 12.

$\left. \begin{array}{l} \frac{3}{4} \text{AgBr} \\ \frac{1}{4} \text{AgI} \end{array} \right\}$  Stained with erythrosin and cyanin.

FIG. 13.

Edwards' isochromatic.

FIG. 14.

Edwards' isochromatic treated with cyanin.
